Abstract—The purpose of this study was to determine the effect of a 10-week training program on the heart rate (HR) and heart rate reserve (HRR) of sedentary middle-aged men. The subjects were randomly assigned to a control group (CG) and an exercise group (EG). The EG performed a 10-week training program consisting of 3 sessions per week of aerobic exercise. The CG did not exercise. The HR and HRR were measured at rest and during a maximal exercise test at baseline and after 10 weeks. The EG showed a significant decrease in HR and HRR at rest and during maximal exercise compared to the CG. The results suggest that a 10-week training program can improve the cardiovascular fitness of sedentary middle-aged men.
